

Naming Conventions

When writing code in Python and other programming languages, we need to give names to different things like variables, functions, and classes. Popular naming conventions include **camelCase** and **snake_case**.

camelCase is a convention where each word in a name starts with a capital letter except for the first word, which starts with a lowercase letter. For example, *firstName*, *totalAmount*, and *numberOfYears* are all written in camelCase. **PascalCase** is a similar convention that also capitalizes the first word, like *LikeThis*.

snake_case is where words are separated by underscores and all letters are lowercase. For example, *first_name*, *total_amount*, and *number_of_years* are all written in snake_case. In Python, snake_case is the **preferred** way of naming variables, functions, and classes.

When it comes to choosing a naming convention, it's mostly up to personal preference and the style guide being used. However, it's important to keep the naming conventions consistent within a project or organization to make sure the code is easy to read and maintain.

Personally, I like to use **camelCase** for functions, **snake_case** for variables, and **PascalCase** for classes. This makes it easier to tell at a glance what something is.
